1 Syllabus

- 1. Asymptotic notation, recurrence.
- 2. Divide and Conquer.
- 3. Dynamic Programming.
- 4. Greedy Algorithm.
- 5. Graph Algorithm.
- 6. NPC

2 Basic

2.1 What is an algorithm?

Unambiguous, mechanically executable sequence of elementary operations.

There are certain types of algorithm:

Traditional (This courses main focus.)	Modern algorithm research
Deterministic	Randomized
Exact	Approximate
Off-line	On-line
Sequential	Parallel

2.2 Input & Output

View algorithm as a function with well defined inputs mapping to specific outputs. For example:

```
Input: A[1...n] // Positive real number, distinct.
Output: MAXA[i], 1 \le i \le n.
```

2.2.1 Algorithm 1

Stupid way.

Algorithm 1 Stupid Find Max Algorithm

```
1: procedure FINDMAX
2:
       for i = 1 to n do
          count = 0
3:
          for j = 1 to n do
4:
             if A[i] > A[j] then
5:
                 count = count + 1
6:
             end if
7:
          end for
8:
          if count = n then
9:
             return A[i]
10:
          end if
11:
12:
      end for
13: end procedure
```

Analysis: Worst Case, n^2 comparison.

2.2.2 Algorithm 2

Sort & Find.

Algorithm 2 Sort & Find Max Algorithm

```
1: procedure FINDMAX

2: \overline{A} = sort(A)

3: return \overline{A}[n]

4: end procedure
```

Analysis: Worst Case, sorting takes $c n \log n$ time.

2.2.3 Algorithm 3

Dynamically store the biggest one.

Algorithm 3 Search & Find Max Algorithm

```
1: procedure FINDMAX
2:
     current = 1
     for i = 2 to n do
3:
         if A[i] > A[current] then
4:
            current = i
5:
         end if
6:
7:
     end for
     return A[current]
8:
9: end procedure
```

2.3 Can we do better?

It depends on the operations allowed. For example the dropping the curtain and find the first appearing one.

3 Asymptotic Notation – big "O" notation

3.1 Growth of Functions

The growth of function in table 1 increase downwards.

Table 1: Function List
$$\log_{10} n$$
 | binary search input pairs $10^{10}n^{10}$ | $1.000.1^n$ | Binary string of length n Permutation

Let f(n), g(n) be function.

3.2 big "O" notation

Definition 3.2.1. $f(n) = \mathcal{O}(g(n))$, if $\exists n_0 \in \mathbb{N}, c \in \mathbb{R}^+$, s.t. $\forall n \geq n_0, f(n) \leq c * g(n)$, and $\lim_{n \to \infty} \frac{f(n)}{g(n)} \neq \infty$, i.e. it is $\lim_{n \to \infty} \frac{f(n)}{g(n)} < k$, for some constant k.

Table 2 shows the basic definition of all the asymptotic notations.

Table 2: Definition for all Asymptotic Notation

f(n)	$\lim_{n\to\infty}\frac{f(n)}{g(n)}$	relation
$\mathcal{O}(g(n))$	$\neq \infty$	<u> </u>
$\Omega(g(n))$	$\neq \infty$	\leq
$\Theta(g(n))$	=k>0	=
o(g(n))	=0	<
$\omega(g(n))$	$=\infty$	>

3.3 Asymptotic Relation's feature

Theorem 3.3.1. Multiplying by positive constant does NOT change asymptotic relations. i.e. if $f(n) = \mathcal{O}(g(n))$, then $100 * f(n) = \mathcal{O}(g(n))$.

Proof:
$$f(n) = \mathcal{O}(g(n)) \Rightarrow \exists n_0 \exists c, \forall n \geq n_0, f(n) \leq c * g(n),$$
 then, $\exists n_0 \exists c', \text{ s.t. } \forall n \geq n_0, 100 * f(n) \leq c' * g(n) = 100c * g(n). \square$ Example:

$$C * 2^n = \Theta(2^n) \tag{1}$$

$$(C*2)^n \neq \Theta(2^n) \tag{2}$$

Claim 3.3.2. *Show:* $2n \log(n) - 10n = \Theta(n \log(n))$

Proof: First show: $2n \log(n) - 10n = \mathcal{O}(n \log(n))$ For $n_0 = 1$, c = 2

$$2n\log(n) - 10n \le 2n\log(n)$$

Now show: $2n \log(n) - 10n = \Omega(n \log(n))$ For $n_0 = 2^1 0$, c = 1,

$$2n \log(n) - 10n \ge n \log(n) + n \log(2^{10}) - 10n$$
$$= n \log(n) + 10n - 10n$$
$$= n \log(n)$$

 $n_0 = 1 \ (n_0 = 2^{10})$ means n is at least 1 (or 2^{10}). \square

Corollary 3.3.3. $\mathcal{O}(1)$ means Any Constant.

Attention: Asymptotic notation has limit. It is not applicable for all scenarios.

3.4 Properties of log(n)

Definition 3.4.1. $n = C^{\log_c n}, c > 1, \lg n = \log_2 n, \ln n = \log_e n.$

Corollary 3.4.2. $\forall a, b > 1$

$$\log_b(n) = \frac{\log_a(n)}{\log_a(b)}$$

$$\log_b(n) = \Theta(\log_a(n))$$
(3)

Corollary 3.4.3. $\forall a, b \in \mathbb{R}$

$$\log(a^n) = n * \log(a)$$

$$\log(a * b) = \log(a) + \log(b))$$

$$a^{\log(b)} = b^{\log(a)}$$
(4)

Note: $\lg(n)$ is to n as n is to 2^n .

3.5 Something More

Theorem 3.5.1. Let f(n) be a polynomial function, then $\log(f(n)) = \Theta(\log(n))$.

Proof: The asymptotic result of n^2 and n^10 are the same. \square

Definition 3.5.2. $\log^*(n) = o(\log \log \log \log \log (n)) = \alpha$.

Example: $\lg^*(2^{2^{2^{2^2}}}) = 5$.

4 Series

4.1 Some Definition

Definition 4.1.1. Harmonic Series:

$$\sum_{i=1}^{n} \frac{1}{i} = \Theta(\log(n))$$

Definition 4.1.2. Geometric Series:

$$\sum_{i=0}^{n-1} x^i = \frac{x^n - 1}{x - 1} = \begin{cases} \Theta(x^n) & \text{if } \forall x > 1, \\ \Theta(1) & \text{if } \forall x < 1, \\ \Theta(n) & \text{if } \forall x = 1. \end{cases}$$

Definition 4.1.3. Arithmetic Series:

$$\sum_{i=1}^{n} i = \frac{n(n+1)}{2} = \Theta(n^2)$$

4.2 Some Theorem

Suppose I want to know if f(n) = o(g(n)).

Theorem 4.2.1. If $\log(f(n)) = o(\log(g(n)), \text{ then } f(n) = o(g(n)).$

Example: Let $f(n) = n^3$, $g(n) = 2^n$. Then $\log(f(n)) = \log(n^3) = 3\log(n)$, $\log(g(n)) = \log(2^n) = n$.

i.e.
$$\log(f(n)) < \log(g(n) \Rightarrow f(n) < g(n)$$

Note that this theorem stands for 'o', NOT TRUE for 'O'.

Example: $\log(n^3) = \mathcal{O}(\log(n^2))$, but $n^3 \neq \mathcal{O}(n^2)$.

5 Induction

5.1 When to use?

Prove statement for all $n \in \mathbb{N}$, s.t. $n \geq n_0$.

5.2 Definition

Basically, induction has two parts:

1. Base case(s) – Sometimes there are more than one base cases.

Prove statement for some n. – Often $n_0 = 0$ or 1.

2. Induction Hypothesis

Assume statement hold true for all $m \leq n$.

Prove the hypothesis implies that it hold true for n + 1.

Note that the process may be different from previous, which just hypothesize n-1 is true and prove for n.

5.3 Example

5.3.1 Good Induction:

Claim: $\sum_{i=1}^{n} i = \frac{n(n+1)}{2}$

Proof: We are required to prove $\forall n > 0, \ \sum_{i=1}^{n} i = \frac{n(n+1)}{2}$.

Base Case: $n=1, \sum_{i=1}^{1} i=1=\frac{1\times(1+1)}{2}$. Hence the claim holds true for n=1.

Induction step: Let k > 1 be an arbitrary natural number.

Let us assume the induction hypothesis: for every k < n, assume $\sum_{i=1}^{k} i = \frac{k(k+1)}{2}$. We will prove $\sum_{i=1}^{k+1} i = \frac{(k+1)(k+2)}{2}$

$$\sum_{i=1}^{k+1} i = \left(\sum_{i=1}^{k} i\right) + (n+1) = \frac{k(k+1)}{2} + \frac{2(k+1)}{2} = \frac{(k+1)(k+2)}{2} \tag{5}$$

Thus establishes the claim for k + 1.

Conclusion: By the principle of mathematical induction, the claim holds for all n. \square

5.3.2 Bad Induction: Prove all horses are the same color

The process is omitted. The key point is that: if the base case is not true for induction hypothesis, the induction will not be solid.

6 Recursion (Divide & Conquer)

- Recursion is like Induction's twin brother, whereas induction is similar to movie filmed, and recursion is similar to movie backward.
- Recursion design may be most important course topic.
- Recursion is a type of reduction. ¹

6.1 Definition of Recursion: a Powerful type of reduction

- 1. if problem size very small (think $\mathcal{O}(1)$), just solve it.
- 2. reduce to one or more small instances of some problem.

Question: How are the smaller (but not $\mathcal{O}(1)$ size) problem solved? Not your problem! Handled by the recursion fairy.

6.2 Tower of Hanoi

- 3 pegs, which hold n distinct sized disks.
- initially *tmp*, *dst* empty and *src* has all disks sorted.
- 3 rules:
 - 1. larger cannot be placed on smaller.
 - 2. only one disks can move at a time.
 - 3. move all disks to dst.

Question: How long until the world end?

Solution

¹Reduction is to solve problem A using a black box for B. Typically B is smaller.

7 Dynamic Programming

7.1 Rod Cutting

- steel rod of length n, where n is some integer.
- P[1...n], where P[i] is market price for rod of length i.

Question:

Suppose you can cut rod to any integer length for free. How much money can you made?

Analysis:

• Consider leftmost cut of optimal solution.

cut can be at positions 1...n.

If leftmost cut at i, then you get P[i] for leftmost piece and then optimally sell remaining n-i length rod.

• Don't know where to make first cut, so try them all and find

$$\max(0, \max(P[i] + cutRod(n-i)))$$

So, the first attempt of the algorithm could be described as algorithm 4.

Algorithm 4 First Attempt of Solving Cutting Rod Problem

```
1: procedure Cutron(n)
       if n = 0 then
2:
                                                               \triangleright If the remaining rod length is 0. \triangleleft
           return 0
3:
       end if
       q = 0
5:
       for i = 1 to n do
           q = \max(q, P[i] + \text{CutRod}(n-i))
7:
8:
       end for
9:
       return q
10: end procedure
```

Running time of algorithm $4:T(n) = n + \sum_{i=0}^{n-i} T(i)$, which is clearly **Exponential** since there are a lot of subproblem overlap!

7.1.1 Memoized Version

algorithm 5 illustrates the memoized version of the algorithm in algorithm 4

Algorithm 5 Memoized Version of Solving Cutting Rod Problem

```
1: procedure MemRodCut(n)

ightharpoonup Globally define R[1..n] 	riangleleft
2:
       if n = 0 then
           return 0
3:
       end if
4:
       if R[n] undefined then
5:
           q = 0
6:
           for i = 1 to n do
7:
               q = \max(q, P[i] + \text{MEMRODCUT}(n-i))
8:
           end for
9:
10:
           R[n] = q
       end if
11:
       return R[n]
12:
13: end procedure
```

Note that R[1...n] is filled in form <u>left to right</u>. It means we can store the result and use it later, which brings us to the dynamic programming version of the algorithm.

7.1.2 Dynamic Programming Version

algorithm 6 illustrates the dynamic programming version of the algorithm according to the memoized version algorithm 5.

Algorithm 6 Dynamic Programming Version of Solving Cutting Rod Problem

```
1: procedure DPRodCut(n)
2:
       Let R[0...n] be an array.
       R[0] = 0
3:
       for j = 1 to n do
4:
          q = 0
5:
          for i = 0 to j do
6:
             q = \max(q, P[i] + R[j - i])
7:
          end for
8:
          R[i] = q
9:
       end for
10:
       return R[n]
11:
12: end procedure
```

Running time of algorithm 6: $T(n) = \mathcal{O}(n^2)$.

Note that the process only computes the total number. If we are to know how to cut, we can store the cutting position during the progress.

Define C[1...n], and replace the inner for loop in algorithm 6 as:

Algorithm 7 Store the Cutting Position in the Process

```
1: for i = 0 to j do
2: q = \max(q, P[i] + R[j - i])
3: C[j] = i
4: end for
5: R[i] = q
```

The for loop does the following:

- C[j] stores last leftmost cut length for rod of length j.
- C[n] says where to make first

Thus C[n-C[n]] tells the second cut.

7.2 Solving DP problem

According to previous examples, we can summarize the general method to solve DP problem.

- 1. Write recursive solution, explain why the solution is correct.
- 2. Identify all subproblems considered.
- 3. Described how to store subproblems.
- 4. Find order to evaluate subproblems, s.t. subproblems you depend on evaluated *before* current subproblem.
- 5. Running Time: time to fill an entry X size table.
- 6. Write DP/Memoized algorithm.

7.3 Longest Increasing Subsequence (LIS)

7.3.1 Description of Problem

Input: Array A[1...n] of integers. Output: Longest subsequence of indices, $1 \le i_1 < i_2 < ... < i_k < n$, s.t. $A[i_j] < A[i_{j+1}]$ for all j.

Warning: Subarray is "contiguous". So what is a subsequence?

- if n = 0, the onl subsequence is empty sequence.
- otherwise, a subsequence is either
 - 1. a subsequence of A[2...n]or,
 - 2. A[1] followed by the subsequence of A[2...n].

7.3.2 Analysis

Suggest recursive strategy for any array subsequence problem.

- if empty, do nothing.
- otherwise figure out whether to take A[1] and let recursion fairy handle A[2...n].

However, the definition of the subsequence is not fully recursive as stated, causing handling A[2...n] depends on whether take A[1].

To fix it, define LIS subsequence with all elements greater than some value as follow.

- LIS(prev, start) be the LIS in A[start, n], s.t. all elements greater then A[prev].
- Augment A s.t $A[0] = -\infty$, then LIS of A[1...n] is LIS(0, 1).

Note that the idea of adding a A[0] maybe useful in many scenarios.

Algorithm 8 Original Algorithm for LIS Problem

```
1: procedure LIS(prev, start)
                                                                                    \triangleright prev < start \triangleleft
       if start > n then
2:
           return 0
3:
       end if
4:
       ignore = LIS(prev, start + 1)
5:
6:
       best = ignore
       if A[start] > A[prev] then
7:
           include = 1 + LIS(start, start + 1)
8:
9:
           if include > ignore then
               best = include
10:
           end if
11:
12:
       end if
       return best
13:
14: end procedure
```

LIS (prev, start) is the length of longest increasing subsequence in A[start...n], s.t. all elements greater than A[prev].

Analysis:

- LIS (prev, start) depends on LIS (prev, start + 1)
- So need 2D table B[0...n][1...n+1], each entry takes O time to fill in, and can fill in any order, s.t. B[][start+1] filled before B[][start].
